WHITE BOX TESTING

- White box testing is a way of testing the external functionality of the code by examining and testing the program code (its code, logic, and how it works internally) that realizes the external functionality.
- This is also known as Clear-box or Open-box or Glass-box testing.
- In this type of testing, the code is visible to the tester. Even though the goal is to make sure the program behaves correctly on the outside (what the user sees), testers do this by examining and testing the actual code that makes those features work.

Why do we use White Box Testing?

- It helps find mistakes that happen when converting requirements into code.
- It also catches errors made by programmers or caused by the programming language.
- Since code shows what the product really does, checking the code helps us understand the real behavior of the software.

White box testing is divided into two main types:

1. Static Testing

- This type of testing looks at the source code without running it.

- i. Desk checking (manually reading code)

- ii. Code walkthrough

- iii. Code inspection

2. Structural Testing

- This type involves checking how the code is structured by testing:

- i. Unit/code functional testing

- ii. Code coverage

- iii. Code complexity

Thank you
